## Problem Set 7, Nov 8, 2018 (Theory Questions Part)

## 2. Support Vector Machines using Coordinate Descent

1. The dual objective function that we have to optimize is the following :

$$\begin{array}{ll} \text{maximize} & f(\boldsymbol{\alpha}) = \boldsymbol{\alpha}^{\top} \mathbf{1} - \frac{1}{2\lambda} \boldsymbol{\alpha}^{\top} \boldsymbol{Q} \boldsymbol{\alpha} \\ \text{subject to} & \boldsymbol{\alpha} \in [0,1]^N \end{array}$$

where  $Q := \text{diag}(y)XX^{\top}\text{diag}(y)$ . For computing coordinate update for one coordinate n, consider the following one variable sub-problem:

$$\label{eq:force_en} \begin{aligned} & \underset{\gamma \in \mathbb{R}}{\text{maximize}} & & f(\pmb{\alpha} + \gamma \pmb{e}_n) \\ & \text{subject to} & & 0 \leq \alpha_n + \gamma \leq 1 \end{aligned}$$

where  $e_n = [0, \cdots, 1, \cdots, 0]^{\top}$  (all zero vector except at the  $n^{\text{th}}$  position). Note that  $\gamma = 0$  (no need to update  $\alpha_n$ ) is an optimum iff  $\nabla_n^P f(\alpha) = 0$ , where  $\nabla_n$  denotes the  $n^{\text{th}}$  component of the gradient, and  $\nabla_n^P f(\alpha)$  is the projected gradient of f, projected onto the box or interval constraint.  $\nabla_n^P f(\alpha)$  can be computed as

$$\nabla_n^P f(\alpha) = \begin{cases} \nabla_n f(\alpha) & \text{if } 0 < \alpha_n < 1\\ \min\{0, \nabla_n f(\alpha)\} & \text{if } \alpha_n = 0\\ \max\{0, \nabla_n f(\alpha)\} & \text{if } \alpha_n = 1 \end{cases}$$

Note that,  $\nabla f(\alpha) = \mathbf{1} - \frac{1}{2\lambda}(Q + Q^{\top})\alpha = \mathbf{1} - \frac{1}{\lambda}Q\alpha$  (Q is symmetric) and thus  $\nabla_n f(\alpha) = 1 - \frac{1}{\lambda}e_n^{\top}Q\alpha$ . Simplifying  $f(\alpha + \gamma e_n)$ , we get

$$f(\boldsymbol{\alpha} + \gamma \boldsymbol{e}_n) = (\boldsymbol{\alpha} + \gamma \boldsymbol{e}_n)^{\top} \mathbf{1} - \frac{1}{2\lambda} (\boldsymbol{\alpha} + \gamma \boldsymbol{e}_n)^{\top} \boldsymbol{Q} (\boldsymbol{\alpha} + \gamma \boldsymbol{e}_n)$$

$$= \boldsymbol{\alpha}^{\top} \mathbf{1} - \frac{1}{2\lambda} \boldsymbol{\alpha}^{\top} \boldsymbol{Q} \boldsymbol{\alpha} + \gamma - \frac{1}{2\lambda} (\gamma^2 \boldsymbol{e}_n^{\top} \boldsymbol{Q} \boldsymbol{e}_n + \gamma \boldsymbol{\alpha}^{\top} \boldsymbol{Q} \boldsymbol{e}_n + \gamma \boldsymbol{e}_n^{\top} \boldsymbol{Q} \boldsymbol{\alpha})$$

$$= f(\boldsymbol{\alpha}) - \frac{\gamma^2}{2\lambda} \boldsymbol{Q}_{nn} + \gamma (1 - \frac{1}{\lambda} \boldsymbol{\alpha}^{\top} \boldsymbol{Q} \boldsymbol{e}_n)$$

Differentiating with respect to  $\gamma$  and equating to 0, we get :

$$-\frac{\gamma^{\star}}{\lambda} \mathbf{Q}_{nn} + (1 - \frac{1}{\lambda} \boldsymbol{\alpha}^{\top} \mathbf{Q} \boldsymbol{e}_{n}) = 0$$
$$\gamma^{\star} = \frac{\lambda}{\mathbf{Q}_{nn}} (1 - \frac{1}{\lambda} \boldsymbol{\alpha}^{\top} \mathbf{Q} \boldsymbol{e}_{n})$$

Note that  $Q_{nn} = \boldsymbol{x}_n^{\intercal} \boldsymbol{x}_n y_n^2 = \boldsymbol{x}_n^{\intercal} \boldsymbol{x}_n$  and  $\boldsymbol{\alpha}^{\intercal} Q \boldsymbol{e}_n = \sum_{i=1}^N \alpha_i Q_{i,n} = \sum_{i=1}^N \alpha_i y_i \boldsymbol{x}_i^{\intercal} \boldsymbol{x}_n y_n$ . Using  $\boldsymbol{w}(\boldsymbol{\alpha}) = \frac{1}{\lambda} \sum_{i=1}^N \alpha_i y_i \boldsymbol{x}_i$ , we get  $\boldsymbol{\alpha}^{\intercal} Q \boldsymbol{e}_n = \lambda y_n \boldsymbol{w}^{\intercal} \boldsymbol{x}_n$  and thus

$$\gamma^{\star} = \frac{\lambda}{\boldsymbol{x}_{n}^{\top} \boldsymbol{x}_{n}} (1 - y_{n} \boldsymbol{w}^{\top} \boldsymbol{x}_{n})$$

We conclude

$$\begin{split} \alpha_n^{\mathsf{new}} &= \alpha_n^{\mathsf{old}} + \gamma^\star \\ &= \alpha_n^{\mathsf{old}} + \frac{\lambda}{\boldsymbol{x}_n^\top \boldsymbol{x}_n} (1 - y_n \boldsymbol{w}^\top \boldsymbol{x}_n) \end{split}$$

Since  $\alpha \in [0,1]^N$ , we project  $\alpha_n$  as

$$\alpha_n^{\mathsf{new}} := \min \Big\{ \max \Big\{ \alpha_n^{\mathsf{old}} + \frac{\lambda}{\boldsymbol{x}_n^{\top} \boldsymbol{x}_n} (1 - y_n \boldsymbol{w}^{\top} \boldsymbol{x}_n), 0 \Big\}, 1 \Big\}$$

## 3. Kernels

- 1. Note that every term in the resulting polynomial is a product of kernels and that all these terms have positive coefficients. Hence the result follows by the two statements proved in class: namely that the positive sum of valid kernels is a valid kernel and that the product of valid kernels is a valid kernel.
- 2. We have  $\exp(x) = \sum_{i \geq 0} \frac{x^i}{i!}$ . We can hence apply the previous result concerning polynomials with positive coefficients and apply the limit.
