Motivation

The ridge solution $\mathbf{w}^* \in \mathbb{R}^D$ has a counterpart $\alpha^* \in \mathbb{R}^N$. Using duality, we will establish a relationship between \mathbf{w}^{\star} and $\boldsymbol{\alpha}^{\star}$ which leads the way to kernels.

Ridge regression

Recall the ridge regression problem

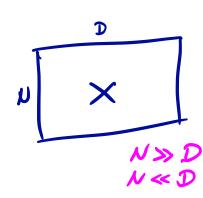

$$\min_{\mathbf{W}} \left(\frac{1}{2} \|\mathbf{y} - \mathbf{X}\mathbf{w}\|^2 + \frac{\lambda}{2} \|\mathbf{w}\|^2 \right)$$

For its solution, we have that

$$\mathbf{w}^{\star} = \mathbf{X}^{\top} \mathbf{X} + \lambda \mathbf{I}_{D})^{-1} \mathbf{X}^{\top} \mathbf{y}$$

$$= \mathbf{X}^{\top} \mathbf{X} \mathbf{X}^{\top} + \lambda \mathbf{I}_{N})^{-1} \mathbf{y} =: \mathbf{X}^{\top} \boldsymbol{\alpha}^{\star},$$

where $\boldsymbol{\alpha}^{\star} := (\mathbf{X}\mathbf{X}^{\top} + \lambda \mathbf{I}_N)^{-1}\mathbf{y}$.

Q2(w) = 0

Lenna:

This can be proved using the following identity: let **P** be an $N \times M$ matrix while **Q** be $M \times N$,

Assumption:

$$|PQ + I_N|$$
 invertible
 $|QP + I_D|$ invertible

 $\frac{P \otimes \mathbf{f}}{P \otimes \mathbf{f}} : (PQ + \mathbf{I}_N)^{-1} \mathbf{P} = \mathbf{P}(\mathbf{QP} + \mathbf{I}_M)^{-1} \Leftrightarrow P(\mathbf{QP} + \mathbf{I}_N) = P \Leftrightarrow P(\mathbf{QP} + \mathbf{I}_N) = P$ A PQP+P=PQP+P & tre

What are the computational complexities for the above two ways of computing \mathbf{w}^* ?

$$COSE$$

$$D : O(D^3 + D^2N)$$

$$D : O(N^3 + N^2D)$$

With this, we know that $\mathbf{w}^* =$ $\mathbf{X}^{\mathsf{T}} \boldsymbol{\alpha}^{\star}$ lies in the column space of \mathbf{X}^{\top} ,

where
$$\mathbf{X} = \begin{bmatrix} \frac{x_{11} & x_{12} & \dots & x_{1D}}{x_{21} & x_{22} & \dots & x_{2D}} \\ \vdots & \vdots & \ddots & \vdots \\ x_{N1} & x_{D2} & \dots & x_{ND} \end{bmatrix} \times_{\mathbf{N}}^{\mathbf{T}}$$

The representer theorem

The representer theorem generalizes this result: for a \mathbf{w}^* minimizing the following function for any \mathcal{L}_n ,

$$\min_{\mathbf{W}} \sum_{n=1}^{N} \mathcal{L}_n(\mathbf{x}_n^{\mathsf{T}}\mathbf{w}, y_n) + \frac{\lambda}{2} ||\mathbf{w}||^2$$

there exists
$$\alpha^*$$
 such that $\mathbf{w}^* = \mathbf{X}^\top \alpha^*$.

Such a general statement was originally proved by Schölkopf, Herbrich and Smola (2001).

Kernelized ridge regression

The representer theorem allows us to write an equivalent optimization problem in terms of α . For example, for ridge regression, the following two problems are equivalent:

use

$$\mathbf{w}^* = \arg\min_{\mathbf{w}} \quad \frac{1}{2} ||\mathbf{y} - \mathbf{X}\mathbf{w}||^2 + \frac{\lambda}{2} ||\mathbf{w}||^2$$

$$\mathbf{w}^{*} = \arg\min_{\mathbf{w}} \quad \frac{1}{2} \|\mathbf{y} - \mathbf{X}\mathbf{w}\|^{2} + \frac{\lambda}{2} \|\mathbf{w}\|^{2}$$

$$\mathbf{w}^{*} = \arg\max_{\mathbf{\alpha}} \quad -\frac{1}{2} \boldsymbol{\alpha}^{\top} (\mathbf{X}\mathbf{X}^{\top} + \lambda \mathbf{I}_{N}) \boldsymbol{\alpha} + \lambda \boldsymbol{\alpha}^{\top} \mathbf{y}$$

$$\mathbf{w}^{*} = \arg\max_{\mathbf{\alpha}} \quad -\frac{1}{2} \boldsymbol{\alpha}^{\top} (\mathbf{X}\mathbf{X}^{\top} + \lambda \mathbf{I}_{N}) \boldsymbol{\alpha} + \lambda \boldsymbol{\alpha}^{\top} \mathbf{y}$$

$$\mathbf{w}^{*} = \arg\max_{\mathbf{\alpha}} \quad -\frac{1}{2} \boldsymbol{\alpha}^{\top} (\mathbf{X}\mathbf{X}^{\top} + \lambda \mathbf{I}_{N}) \boldsymbol{\alpha} + \lambda \boldsymbol{\alpha}^{\top} \mathbf{y}$$

they both have the same i.e. optimal value. Also, we can always have the correspondence mapping $\mathbf{w}^* = \mathbf{X}^{\top} \boldsymbol{\alpha}_{\cdot}^*$

$$(XX^T)_{ij} = x_i^T x_j$$

importantly, the Most second problem is expressed in terms of the matrix $\mathbf{X}\mathbf{X}^{\top}$. This is our first example of a kernel matrix.

Note: We don't give a detailed derivation of the second problem, but to show the equivalence, you can show that we obtain equal optimal values for the two problems. You can find a derivation of this duality here: http://www.ics.uci.edu/ ~welling/classnotes/papers_class/ Kernel-Ridge.pdf.

Advantages of kernelized ridge regression

First, it might be computationally efficient in some cases when solving the system of equations.

 $\mathcal{N} \! \ll \! \mathcal{D}$ レシカ

Second, by defining $(\mathbf{K}) = \mathbf{X} \mathbf{X}^{\mathsf{T}}$, we can work directly with \mathbf{K} and never have to worry about **X**. This is the kernel trick.

Third, working with α is sometimes advantageous, and provides additional information for each datapoint (e.g. as in SVMs).

Kernel functions

The linear kernel is defined below:

$$\mathbf{K} = \mathbf{X}\mathbf{X}^{\top} = \begin{bmatrix} \mathbf{x}_1^{\top}\mathbf{x}_1 & \mathbf{x}_1^{\top}\mathbf{x}_2 & \dots & \mathbf{x}_1^{\top}\mathbf{x}_N \\ \mathbf{x}_2^{\top}\mathbf{x}_1 & \mathbf{x}_2^{\top}\mathbf{x}_2 & \dots & \mathbf{x}_2^{\top}\mathbf{x}_N \\ \vdots & \vdots & \ddots & \vdots \\ \mathbf{x}_N^{\top}\mathbf{x}_1 & \mathbf{x}_N^{\top}\mathbf{x}_2 & \dots & \mathbf{x}_N^{\top}\mathbf{x}_N \end{bmatrix}.$$

K_{ij} = *; *;

Kernel with basis functions $\phi(\mathbf{x})$

Kernel with basis functions
$$\boldsymbol{\phi}(\mathbf{x})$$
 with $\mathbf{K} := \boldsymbol{\Phi}^{\top} \boldsymbol{\Phi}$ is shown below:
$$\begin{bmatrix} \boldsymbol{\phi}(\mathbf{x}_1)^{\top} \boldsymbol{\phi}(\mathbf{x}_1) & \boldsymbol{\phi}(\mathbf{x}_1)^{\top} \boldsymbol{\phi}(\mathbf{x}_2) & \dots & \boldsymbol{\phi}(\mathbf{x}_1)^{\top} \boldsymbol{\phi}(\mathbf{x}_N) \\ \boldsymbol{\phi}(\mathbf{x}_2)^{\top} \boldsymbol{\phi}(\mathbf{x}_1) & \boldsymbol{\phi}(\mathbf{x}_2)^{\top} \boldsymbol{\phi}(\mathbf{x}_2) & \dots & \boldsymbol{\phi}(\mathbf{x}_2)^{\top} \boldsymbol{\phi}(\mathbf{x}_N) \\ \vdots & \vdots & \ddots & \vdots \\ \boldsymbol{\phi}(\mathbf{x}_N)^{\top} \boldsymbol{\phi}(\mathbf{x}_1) & \boldsymbol{\phi}(\mathbf{x}_N)^{\top} \boldsymbol{\phi}(\mathbf{x}_2) & \dots & \boldsymbol{\phi}(\mathbf{x}_N)^{\top} \boldsymbol{\phi}(\mathbf{x}_N) \end{bmatrix}.$$

the kernel matrix

The kernel trick

A big advantage of using kernels is that we do not need to specify $\phi(\mathbf{x})$ explicitly, since we can work directly with \mathbf{K} .

 $x_n^T = IIII$ original space $\int \Phi(x_n) = IIIIIII$ feature space

We will use a kernel function $\kappa(\mathbf{x}, \mathbf{x}')$ and compute the (i, j)-th entry of \mathbf{K} as $K_{ij} = \kappa(\mathbf{x}_i, \mathbf{x}_j)$. A kernel function κ is usually associated with a feature map $\boldsymbol{\phi}$, such that

$$\kappa(\mathbf{x}, \mathbf{x}') := \phi(\mathbf{x})^{\mathsf{T}} \phi(\mathbf{x}')$$
.

For example, for the linear kernel $\kappa(\mathbf{x}, \mathbf{x}') := \mathbf{x}^{\top} \mathbf{x}'$, the feature map is just the original features, $\phi(\mathbf{x}') = \mathbf{x}'$.

Another example: The kernel $\kappa(x,x') := x^2(x')^2$ corresponds to $\phi(x) = x^2$, and $\kappa(\mathbf{x},\mathbf{x}') := (x_1x_1' + x_2x_2' + x_3x_3')^2$ corresponds to

$$K(x,x') := (x^T x')^2$$

$$\boldsymbol{\phi}(\mathbf{x})^{\top} = \begin{bmatrix} x_1^2, & x_2^2, & x_3^2, & \sqrt{2}x_1x_2, & \sqrt{2}x_1x_3, & \sqrt{2}x_2x_3 \end{bmatrix},$$

The good news is that the evaluation of a kernel is often faster when using κ instead of ϕ .

$$K(x,x') = \phi(x)^{\mathsf{T}} \phi(x')$$

Visualization

Why would we want such general feature maps?

See video explaining linear separation in the kernel space (where $\phi(\mathbf{x})$ maps to) corresponding to non-linear separation in the original \mathbf{x} -space: https://www.youtube.com/watch?v=3liCbRZPrZA

Examples of kernels

The above kernel is an example of the polynomial kernel. Another example is the Radial Basis Function (RBF) kernel.

$$\kappa(\mathbf{x}, \mathbf{x}') = \exp\left[-\frac{1}{2}(\mathbf{x} - \mathbf{x}')^{\top}(\mathbf{x} - \mathbf{x}')\right]$$

See more examples in Section 14.2 of Murphy's book.

A natural question is the following: how can we ensure that there exists a ϕ corresponding to a given kernel **K**? The answer is: as long as the kernel satisfies certain properties.

$$Po'_{x}:$$

$$K(x,x') = (x^{T}x')^{T}$$

$$\Phi(x), \dot{\Phi}(x')$$

$$RBF:$$

$$K(x,x') =$$

r(11x-x112)

Properties of a kernel

A kernel function must be an innerproduct in some feature space. Here are a few properties that ensure it is the case.

- 1. **K** should be symmetric, i.e. $\kappa(\mathbf{x}, \mathbf{x}') = \kappa(\mathbf{x}', \mathbf{x})$.
- 2. For any arbitrary input set $\{\mathbf{x}_n\}$ and all N, \mathbf{K} should be positive semi-definite.

An important subclass is the positive-definite kernel functions, giving rise to infinite-dimensional feature spaces.

Is there a
$$\Phi$$
 which produces k ?
$$K(.,.) = \Phi(.) \Phi(.)$$

$$x \in \mathbb{R}^{D}$$

$$\overline{\Phi}(x) \in \mathbb{R}^{\infty}$$

But...

How to do prediction with kernels?

no kernel kernel

 $\Phi(\times_{fresh})$

prediction \times_{fresh} $\Psi(\times_{fresh})$ $\Psi($

Exercises

- 1. Understand the relationship $\mathbf{w}^* = \mathbf{X}^\top \boldsymbol{\alpha}^*$. Understand the statement of the representer theorem.
- 2. Show that the primal and dual formulations of ridge regression are equivalent. Hint: show that the optimization problems corresponding to \mathbf{w} and $\boldsymbol{\alpha}$ have the same optimal value.
- 3. Get familiar with various examples of kernels. See Section 6.2 of Bishop on examples of kernel construction. Read Section 14.2 of Murphy's book for examples of kernels.
- 4. Revise and understand the difference between positive-definite and positive-semi-definite matrices.
- 5. If you are interested in more details about kernels, read about Mercer and Matern kernels from Kevin Murphy's Section 14.2. There is also a small note by Matthias Seeger on the git repository under lectures/07, in particular for the case of infinite dimensional ϕ .
